

Tomato Crop Management Guide

Section 1: General Information

Tomatoes are a warm-season crop that require a significant amount of water.

Section 2: Irrigation Management during Flowering

When the tomato crop is in the flowering stage and water availability is low, it is crucial to implement water-saving practices. You should adopt drip irrigation to deliver water directly to the root zone. Avoid overhead watering to reduce evaporation and disease risk. Maintain consistent soil moisture, but do not overwater. If water is severely limited, prioritize watering during the critical fruit-set period rather than early vegetative growth.

Section 3: Pest Control

Common pests include aphids and whiteflies. Apply neem oil early in the morning.
